## 0 Introduction

Representaiton theory is the theory of how *groups* act as groups of linear transformations on *vector spaces*.

Here the groups are either *finite*, or *compact topological groups* (infinite), for example,  $SU(n)$  and  $O(n)$ . The vector spaces we conside are finite dimensional, and usually over  $\mathbb{C}$ . Actions are *linear* (see below).

Some books: James-Liebeck (CUP); Alperin-Bell (Springer); Charles Thomas, *Representations of finite and Lie groups*; Onlne notes: SM, Teleman; P.Webb *A course in finite group representation theory* (CUP); Charlie Curtis, *Pioneers of representation theory* (history).

## 1 Group actions

Throughout this course, if not specified otherwise:

- $F$  is a field, usually  $\mathbb{C}$ ,  $\mathbb{R}$  or  $\mathbb{Q}$ . When the field is one of these, we are discussing *ordinary representation theory*. Sometimes  $F = F_p$  or  $\bar{F}_p$  (algebraic closure, see Galois Theory), in which case the theory is called *modular representation theory*;
- $V$  is a vector space over  $F$ , always finite dimensional;  
 $GL(V) = \{\theta : V \rightarrow V, \theta \text{ linear, invertible}\}$ , i.e.  $\det \theta \neq 0$ .

Recall from Linear Algebra:

If  $\dim_F V = n < \infty$ , choose basis  $e_1, \dots, e_n$  over  $F$ , so we can identify it with  $F^n$ . Then  $\theta \in GL(V)$  corresponds to an  $n \times n$  matrix  $A_\theta = (a_{ij})$ , where  $\theta(e_j) = \sum_i a_{ij} e_i$ . In fact, we have  $A_\theta \in GL_n(F)$ , the general linear group.

(1.1)  $GL(V) \cong GL_n(F)$  as groups by  $\theta \rightarrow A_\theta$  ( $A_{\theta_1 \theta_2} = A_{\theta_1} A_{\theta_2}$  and bijection).  
 Choosing different basis gives different isomorphism to  $GL_n(F)$ , but:

(1.2) Matrices  $A_1, A_2$  represent the same element of  $GL(V)$  w.r.t different bases iff they are conjugate (similar), i.e.  $\exists X \in GL_n(F)$  s.t.  $A_2 = X A_1 X^{-1}$ .

Recall that  $\text{tr}(A) = \sum_i a_{ii}$  where  $A = (a_{ij})$ , the *trace* of  $A$ .

(1.3)  $\text{tr}(X A X^{-1}) = \text{tr}(A)$ , hence we can define  $\text{tr}(\theta) = \text{tr}(A_{\theta_1})$  independent of basis.

(1.4) Let  $\alpha \in GL(V)$  where  $V$  in f.d. over  $\mathbb{C}$ , with  $\alpha^m = \iota$  for some  $m$  (here  $\iota$  is the identity map). Then  $\alpha$  is diagonalisable.

Recall  $\text{End} V$  is the set of all linear maps  $V \rightarrow V$ , e.g.  $\text{End}(F^n) = M_n(F)$  some  $n \times n$  matrices.

(1.5) *Proposition.* Take  $V$  f.d. over  $\mathbb{C}$ ,  $\alpha \in \text{End}(V)$ . Then  $\alpha$  is diagonalisable iff there exists a polynomial  $f$  with distinct linear factors with  $f(\alpha) = 0$ . For example, in (1.4), where  $\alpha^m = \iota$ , we take  $f = X^m - 1 = \prod_{j=0}^{m-1} (X - \omega^j)$  where  $\omega = e^{2\pi i/m}$  is the  $(m^{\text{th}})$  root of unity. In fact we have:

(1.4)\* A finite family of commuting separately diagonalisable automorphisms of a  $\mathbb{C}$ -vector space can be simultaneously diagonalised (useful in abelian groups).

Recall from Group Theory:

(1.6) The symmetric group,  $S_n = \text{Sym}(X)$  on the set  $X = \{1, \dots, n\}$  is the set of all permutations of  $X$ .  $|S_n| = n!$ . The alternating group  $A_n$  on  $X$  is the set of products of an even number of transpositions (2-cycles).  $|A_n| = \frac{n!}{2}$ .

(1.7) Cyclic groups of order  $m$ :  $C_m = \langle x : x^m = 1 \rangle$ . For example,  $(\mathbb{Z}/m\mathbb{Z}, +)$ ; also, the group of  $m^{\text{th}}$  roots of unity in  $\mathbb{C}$  (inside  $GL_1(\mathbb{C}) = \mathbb{C}^*$ , the multiplicative group of  $\mathbb{C}$ ). We also have the group of rotations, centre  $O$  of regular  $m$ -gon in  $\mathbb{R}^2$  (inside  $GL_2(\mathbb{R})$ ).

(1.8) Dihedral groups  $D_{2m}$  of order  $2m = \langle x, y : x^m = y^2 = 1, yxy^{-1} = x^{-1} \rangle$ . Think of this as the set of rotations and reflections preserving a regular  $m$ -gon.

(1.9) Quaternion group,  $Q_8 = \langle x, y \mid x^4 = 1, y^2 = x^2, yxy^{-1} = x^{-1} \rangle$  of order 8. For example, in  $GL_2(\mathbb{C})$ , put  $i = \begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix}, j = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, k = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}$ , then  $Q_8 = \{\pm I_2, \pm i, \pm j, \pm k\}$ .

(1.10) The conjugacy class (ccls) of  $g \in G$  is  $\mathcal{C}_G(g) = \{xgx^{-1} : x \in G\}$ . Then  $|\mathcal{C}_G(g)| = |G : C_G(g)|$ , where  $C_G(g) = \{x \in G : xg = gx\}$ , the centraliser of  $g \in G$ .

(1.11) Let  $G$  be a group,  $X$  be a set.  $G$  acts on  $X$  if there exists a map  $\cdot : G \times X \rightarrow X$  by  $(g, x) \rightarrow g \cdot x$  for  $g \in G, x \in X$ , s.t.  $1 \cdot x = x$  for all  $x \in X$ ,  $(gh) \cdot x = g \cdot (h \cdot x)$  for all  $g, h \in G, x \in X$ .

(1.12) Given an action of  $G$  on  $X$ , we obtain a homomorphism  $\theta : G \rightarrow \text{Sym}(X)$ , called the *permutation representation* of  $G$ .

*Proof.* For  $g \in G$ , the function  $\theta_g : X \rightarrow X$  by  $x \rightarrow gx$  is a permutation on  $X$ , with inverse  $\theta_{g^{-1}}$ . Moreover,  $\forall g_1, g_2 \in G, \theta_{g_1 g_2} = \theta_{g_1} \theta_{g_2}$  since  $(g_1 g_2)x = g_1(g_2 x)$  for  $x \in X$ .  $\square$

## 2 Basic Definitions

### 2.1 Representations

Let  $G$  be finite,  $F$  be a field, usually  $\mathbb{C}$ .

**Definition.** (2.1)

Let  $V$  be a f.d. vector space over  $F$ . A (linear, in some books) *representation* of  $G$  on  $V$  is a group homomorphism

$$\rho = \rho_V : G \rightarrow GL(V)$$

Write  $\rho_g$  for the image  $\rho_V(g)$ ; so for each  $g \in G$ ,  $\rho_g \in GL(V)$ , and  $\rho_{g_1 g_2} = \rho_{g_1} \rho_{g_2}$ , and  $(\rho_g)^{-1} = \rho_{g^{-1}}$ .

The *dimension* (or *degree*) of  $\rho$  is  $\dim_F V$ .

(2.2) Recall  $\ker \rho \triangleleft G$  (kernel is a normal subgroup), and  $G/\ker \rho \cong \rho(G) \leq GL(V)$  (1st isomorphism theorem). We say  $\rho$  is *faithful* if  $\ker \rho = 1$ .

An alternative (and equivalent) approach is to observe that a representation of  $G$  on  $V$  is "the same as" a *linear action* of  $G$ :

**Definition.** (2.3)

$G$  *acts linearly* on  $V$  if there exists a *linear action*

$$\begin{aligned} G \times V &\rightarrow V \\ (g, v) &\rightarrow gv \end{aligned}$$

By linear action we mean: (action)  $(g_1 g_2)v = g_1(g_2 v)$ ,  $1v = v \ \forall g_1, g_2 \in G, v \in V$ , and (linear)  $g(v_1 + v_2) = gv_1 + gv_2$ ,  $g(\lambda v) = \lambda gv \ \forall g \in G, v_1, v_2 \in V, \lambda \in F$ .

Now if  $G$  acts linearly on  $V$ , the map

$$\begin{aligned} G &\rightarrow GL(V) \\ g &\rightarrow \rho_g \end{aligned}$$

with  $\rho_g : v \rightarrow gv$  is a representation of  $G$ . Conversely, given a representation  $\rho : G \rightarrow GL(V)$ , we have a linear action of  $G$  on  $V$  via  $g \cdot v := \rho(g)v \ \forall v \in V, g \in G$ .

(2.4) In (2.3) we also say that  $V$  is a  $G$ -space or that  $V$  is a  $G$ -module. In fact if we define the *group algebra*  $FG$ , or  $F[G]$ , to be  $\{\sum \alpha_j g : \alpha_j \in F\}$  with natural addition and multiplication, then  $V$  is actually a  $FG$ -module (in the sense from GRM).

(2.5)  $R$  is a *matrix representation* of  $G$  of degree  $n$  if  $R$  is a homomorphism  $G \rightarrow GL_n(F)$ . Given representation  $\rho : G \rightarrow GL(V)$  with  $\dim_F V = n$ , fix basis  $B$ ; we get matrix representation

$$\begin{aligned} G &\rightarrow GL_n(F) \\ g &\rightarrow [\rho(g)]_B \end{aligned}$$

Conversely, given matrix representation  $R : G \rightarrow GL_n(F)$ , we get representation

$$\begin{aligned}\rho : G &\rightarrow GL(F^n) \\ g &\rightarrow \rho_g\end{aligned}$$

via  $\rho_g(v) = R_g v$  where  $R_g$  is the matrix of  $g$ .

**Example.** (2.6)

Given any group  $G$ , take  $V = F$  the 1-dimensional space, and

$$\begin{aligned}\rho : G &\rightarrow GL(F) \\ g &\rightarrow (id : F \rightarrow F)\end{aligned}$$

is known as the trivial representation of  $G$ . So  $\deg \rho = 1$  ( $\dim_F F = 1$ ).

**Example.** (2.7)

Let  $G = C_4 = \langle x : x^4 = 1 \rangle$ . Let  $n = 2$ , and  $F = \mathbb{C}$ . Note that any  $R : x \rightarrow X$  will determine  $x^j \rightarrow X^j$  as it is a homomorphism, and also we need  $X^4 = I$ . So we can take  $X$  to be diagonal matrix – any such with diagonal entries a root to  $x^4 = 1$ , i.e.  $\{\pm 1, \pm i\}$ , or if  $X$  is not diagonal then it will be similar to a diagonal matrix by (1.4) ( $X^4 = I$ ).

## 2.2 Equivalent representations

**Definition.** (2.8)

Fix  $G, F$ . Let  $V, V'$  be  $F$ -spaces, and  $\rho : G \rightarrow GL(V)$ ,  $\rho' : G \rightarrow GL(V')$  which are representations of  $G$ . The linear map  $\phi : V \rightarrow V'$  is a  $G$ -homomorphism if

$$\phi \rho(g) = \rho'(g) \phi \forall g \in G(*)$$

We can understand this more by the following diagram:

$$\begin{array}{ccc} V & \xrightarrow{\rho_g} & V \\ \phi \downarrow & \searrow & \downarrow \phi \\ V' & \xrightarrow{\rho'_{g'}} & V' \end{array}$$

We say  $\phi$  *intertwines*  $\rho, \rho'$ . Write  $\text{Hom}_G(V, V')$  for the  $F$ -space of all these.  $\phi$  is a  $G$ -isomorphism if it is also bijective; if such  $\phi$  exists,  $\rho, \rho'$  are isomorphic/equivalent representations. If  $\phi$  is a  $G$ -isomorphism, we can write (\*) as  $\rho' = \phi\rho\phi^{-1}$ .

**Lemma.** (2.9)

The relation "being isomorphic" is an equivalent relation on the set of all representations of  $G$  (over  $F$ ).

**Remark.** (2.10)

If  $\rho, \rho'$  are isomorphic representations, they have the same dimension.

The converse may be false:  $C_4$  has four non-isomorphic 1-dimensional representations: if  $\omega = e^{2\pi i/4}$  then they are  $\rho_j(x^i) = \omega^{ij}$  ( $0 \leq i \leq 3$ ).

**Remark.** (2.11)

Given  $G, V$  over  $F$  of dimension  $n$  and  $\rho : G \rightarrow GL(V)$ . Fix basi  $B$  for  $V$ : we get a linear isomorphism

$$\begin{aligned} \phi : V &\rightarrow F^n \\ v &\rightarrow [v]_B \end{aligned}$$

and we get a representation  $\rho' : G \rightarrow GL(F^n)$  isomorphic to  $\rho$ :

$$\begin{array}{ccc} V & \xrightarrow{\rho} & V \\ \downarrow \phi & & \downarrow \phi \\ F^n & \xrightarrow{\rho'} & F^n \end{array}$$

(2.12) In terms of matrix representations, we have

$$\begin{aligned} R : G &\rightarrow GL_n(F), \\ R' : G &\rightarrow GL_n(F) \end{aligned}$$

are  $(G)$ -isomorphic or equivalent if there exists a nonsingular matrix  $X \in GL_n(F)$  with  $R'(g) = XR(g)X^{-1} \forall g \in G$ .

In terms of linear  $G$ -actions, the actions of  $G$  on  $V, V'$  are  $G$ -isomorphic if there exists isomorphisms  $\phi : V \rightarrow V'$  such that  $g : \phi(v) = \phi(gv) \forall v \in V, g \in G$ .

### 2.3 Subrepresentations

**Definition.** (2.13)

Let  $\rho : G \rightarrow GL(V)$  be a representation of  $G$ . We say  $W \leq V$  is a  $G$ -subspace if it's a subspace and it is  $\rho(G)$ -invariant, i.e.  $\rho_g(W) \leq W \forall g \in G$ . Obviously  $\{0\}$  and  $V$  are  $G$ -subspaces, however.

$\rho$  is *irreducible/simple* representation if there are no proper  $G$ -subspaces.

**Example.** (2.14)

Any 1-dimensional representation of  $G$  is irreducible, but not conversely, e.g.  $D_8$  has 2-dimensional  $\mathbb{C}$ -irreducible representation.

(2.15) In definition (2.13), if  $W$  is a  $G$ -subspace, then the corresponding map

$$\begin{aligned} G &\rightarrow GL(W) \\ g &\rightarrow \rho(g)|_W \end{aligned}$$

is a representation of  $G$ , a *subrepresentation* of  $\rho$ .

**Lemma.** (2.16)

In definition (2.13), given  $\rho : G \rightarrow GL(V)$ , if  $W$  is a  $G$ -subspace of  $V$  and if  $B = \{v_1, \dots, v_n\}$  is a basis containing basis  $B_1 = \{v_1, \dots, v_m\}$  of  $W$  ( $0 < m < n$ ) then the matrix of  $\rho(g)$  w.r.t.  $B$  has block upper triangular form as the graph below, for

each  $g \in G$ .

**Example.** (2.17)

(i) The irreducible representations of  $C_4 = \langle x : x^4 = 1 \rangle$  are all 1-dimensional and four of these are  $x \rightarrow i, x \rightarrow -1, x \rightarrow -i, x \rightarrow 1$ . In general,  $C_m = \langle x : x^m = 1 \rangle$  has precisely  $m$  irreducible complex representations, all of dimension 1. In fact, all complex irreducible representations of a finite abelian group are 1-dimensional (use (1.4)\* or see (4.4) below).

(ii)  $G = D_6$ : any irreducible  $\mathbb{C}$ -representation has dimension  $\leq 2$ .

Let  $\rho : G \rightarrow GL(V)$  be irreducible  $G$ -representation. Let  $r, s$  be rotation and reflection in  $D_6$  respectively. Let  $V$  be eigenvector of  $\rho(r)$ . So  $\rho(r)v = \lambda v$

for some  $\lambda \neq 0$ . Let  $W = \text{span}\{v, \rho(s)v\} \leq V$ . Since  $\rho(s)\rho(s)v = v$  and  $\rho(r)\rho(s)v = \rho(s)\rho(r)^{-1}v = \lambda^{-1}\rho(s)v$ , both of which are in  $W$ ; so  $W$  is  $G$ -invariant, i.e. a  $G$ -subspace. Since  $V$  is irreducible,  $W = V$ .

**Definition.** (2.18)

We say that  $\rho : G \rightarrow GL(V)$  is *decomposable* if there are proper  $G$ -invariant subspaces  $U, W$  with  $V = U \oplus W$ . Say  $\rho$  is direct sum  $\rho_U \oplus \rho_W$ . If no such decomposition exists, we say that  $\rho$  is *indecomposable*.

**Lemma.** (2.19)

Suppose  $\rho : G \rightarrow GL(V)$  is decomposable with  $G$ -invariant decomposition  $V = U \oplus W$ . If  $B$  is a basis  $\{\underbrace{u_1, \dots, u_k}_{B_1}, \underbrace{w_1, \dots, w_l}_{B_2}\}$  of  $V$  consisting of basis of  $U$  and basis of  $W$ , then w.r.t.  $B$ ,  $\rho(g)_B$  is a block diagonal matrix  $\forall g \in G$  as

$$\rho(g)_B = \begin{pmatrix} [\rho_U(g)]_{B_1} & 0 \\ 0 & [\rho_W(g)]_{B_2} \end{pmatrix}$$

**Definition.** (2.20)

If  $\rho : G \rightarrow GL(V)$ ,  $\rho' : G \rightarrow GL(V')$ , the *direct sum* of  $\rho, \rho'$  is

$$\rho \oplus \rho' : G \rightarrow GL(V \oplus V')$$

where  $\rho \oplus \rho'(g)(v_1 + v_2) = \rho(g)v_1 + \rho'(g)v_2$ , a *block diagonal action*. For matrix representations  $R : G \rightarrow GL_n(F)$ ,  $R' : G \rightarrow GL_{n'}(F)$ , define  $R \oplus R' : G \rightarrow GL_{n+n'}(F)$ :

$$g \rightarrow \begin{pmatrix} R(g) & 0 \\ 0 & R'(g) \end{pmatrix}$$

### 3 Complete reducibility and Maschke's theorem

**Definition.** (3.1)

A representation  $\rho : G \rightarrow GL(V)$  is *completely reducible*, or *semisimple*, if it is a direct sum of irreducible representations. Evidently, irreducible implies completely reducible (lol).

**Remark.** (3.2)

- (1) The converse is false;
- (2) See sheet 1 Q3:  $\mathbb{C}$ -representaiton of  $\mathbb{Z}$  is not completely reducible and also representaiton of  $C_p$  over  $\mathbb{F}_p$  is not c.r..

From now on, take  $G$  finite and  $\text{char } F = 0$ .

**Theorem.** (3.3)

Every f.d. representation  $V$  of a finite group over a field of char 0 is completely reducible, i.e.

$$V \cong V_1 \oplus \dots \oplus V_r$$

is a direct sum of representations, each  $V_i$  irreducible.

It is enough to prove:

**Theorem.** (3.4 Maschke's theorem, 1899)

Let  $G$  be finite,  $\rho : G \rightarrow GL(V)$  a f.d. representation,  $\text{char } F = 0$ . If  $W$  is a  $G$ -subspace of  $V$ , then there exists a  $G$ -subspace  $U$  of  $V$  s.t.  $V = W \oplus U$ , a direct sum of  $G$ -subspaces.

*Proof.* (1)

Let  $W'$  be any *vector subspace* complement of  $W$  in  $V$ , i.e.  $V = W \oplus W'$  as vector spaces, and  $W \cap W' = 0$ . Let  $q : V \rightarrow W$  be th projection of  $V$  onto  $W$  along  $W'$  ( $\ker q = W'$ ), i.e. if  $v = w + w'$  then  $q(v) = w$ . Define

$$\bar{q} : v \rightarrow \frac{1}{|G|} \sum_{g \in G} gq(g^{-1}v)$$

the 'average' of  $q$  over  $G$ . Note that in order for  $\frac{1}{|G|}$  to exist, we need  $\text{char } F \nmid |G|$ .

It still works if  $\text{char } F \nmid |G|$ .

Claim (1):  $\bar{q} : V \rightarrow W$ : For  $v \in V$ ,  $g(q(g^{-1}v)) \in W$  and  $gW \leq W$ ;

Claim (2):  $\bar{q}(w) = w$  for  $w \in W$ :

$$\bar{q}(w) = \frac{1}{|G|} \sum_{g \in G} gq(g^{-1}w) = \frac{1}{|G|} \sum_{g \in G} g(g^{-1}w) = \frac{1}{|G|} \sum_{g \in G} w = w$$

So these two claims imply that  $\bar{q}$  projects  $V$  onto  $W$ .

Claim (3) If  $h \in G$  then  $h\bar{q}(v) = \bar{q}(hv)$  ( $v \in V$ ):

$$\begin{aligned}
 h\bar{q}(v) &= h \frac{1}{|G|} \sum_g g \cdot q(g^{-1}v) \\
 &= \frac{1}{|G|} \sum_g h g q(g^{-1}v) \\
 &= \frac{1}{|G|} \sum_g (hg) q((hg)^{-1}hv) \\
 &= \frac{1}{|G|} \sum_g g q(g^{-1}(hv)) \\
 &= \bar{q}(hv) \\
 &= \bar{q}(hv)
 \end{aligned}$$

We'll then show that the kernel of this map is  $G$ -invariant, so this gives a  $G$ -summand on Thursday.  $\square$
