## 1 Propositional logic

Let  $P$  denote a set of *primitive proposition*, unless otherwise stated,  $P = \{p_1, p_2, \dots\}$ .

The *language* or *set of propositions*  $L = L(P)$  is defined inductively by:

- 1)  $p \in L \ \forall p \in P$ ;
- 2)  $\perp \in L$ , where  $\perp$  is read as 'false';
- 3) If  $p, q \in L$ , then  $(p \implies q) \in L$ . For example,  $(p_1 \implies L)$ ,  $((p_1 \implies p_2) \implies (p_1 \implies p_3))$ .

Note that at this point, each proposition is only a finite string of symbols from the alphabet  $(, ), \implies, \perp, p_1, p_2, \dots$  and do not really mean anything (until we define so).

By *inductively define*, we mean more precisely that we set  $L_1 = P \cup \{\perp\}$ , and  $L_{n+1} = L_n \cup \{(p \implies q) : p, q \in L_n\}$ , and then put  $L = L_1 \cup L_2 \cup \dots$ .

Each proposition is built up *uniquely* from 1) and 2) using 3). For example,  $((p_1 \implies p_2) \implies (p_1 \implies p_3))$  came from  $(p_1 \implies p_2)$  and  $(p_1 \implies p_3)$ . We often omit outer brackets or use different brackets for clarity.

Now we can define some useful things:

- $\neg p$  (not  $p$ ), as an abbreviation for  $p \implies \perp$ ;
- $p \vee q$  ( $p$  or  $q$ ), as an abbreviation for  $(\neg p) \implies q$ ;
- $p \wedge q$  ( $p$  and  $q$ ), as an abbreviation for  $(p \implies (\neg q))$ .
